TASK 4

Business Pattern Interpretation

The analysis of Netflix content by release year shows how the platform's content library has evolved over time. The yearly release counts help identify periods of increasing and decreasing content production.

The trend visualization indicates that Netflix's content library became significantly larger during the more recent years represented in the dataset. Movies generally account for a larger share of the total content, while TV Shows represent a smaller but important portion of the library.

Periods of increasing releases may indicate stronger content expansion and investment, while declines may reflect changes in production, licensing, or the availability of content in the dataset.

From a business perspective, the increasing volume of recent content suggests a strong focus on expanding the content library. The comparison between Movies and TV Shows can also help understand Netflix's content strategy and identify opportunities for further analysis based on genre, country, rating, and release year.

TASK 5

Audience Insights

The rating analysis shows the distribution of Netflix content across different audience-rating categories. This helps identify the types of audiences that are most strongly represented in the dataset.

The genre analysis identifies the most common content categories available on Netflix. The most frequently occurring genres provide an indication of the content preferences and major content segments represented in the platform's library.

Comparing ratings between Movies and TV Shows reveals differences in the audience targeting of the two content types. Some rating categories may be more strongly represented among Movies, while others may have a higher representation among TV Shows.

Overall, the analysis indicates that Netflix maintains a diverse content library covering different genres and audience categories. These insights can support content planning, audience segmentation, recommendation strategies, and future business analysis.
